Thanks for the reply Justin.

After restoring the database in its original state I ran counts on
recordType/userRecordType and got this:

```
recordType userRecordType  count (*)
11 36 376143458
11 34 290102
13 45 63893
14 32 63893
18 255 22941
17 255 228
14 33 2
```

The messages are posted through JMS from inside the same Wildfly
instance that runs ActiveMQ. Message handling is done by MDBs that run
inside the same JVM. We do have some clustered Wildfly setups although
most are standalone.

We know we are running an old version. Upgrading Wildfly is on our
roadmap but that may take quite some time. We investigated upgrading
ActiveMQ separately but ran into too many issues and gave up on that idea.

Content-Type: text/plain; charset="UTF-8"
Content-Transfer-Encoding: quoted-printable

Based on the information you provided I can say that the problem isn't what I originally expected. Here's how the data breaks down per record type:

- Add (11)
 - Set scheduled delivery time (36): 376,143,458
 - Update delivery count (34): 290,102
- Add Transactional (13)
 - Add message (45): 63,893
- Update Transactional (14)
 - Add reference (32) 63,893
 - Acknowledge reference (33) 2
- Prepare (17): 228

./08acc429-acaf-4e0d-943e-aed1e7effc01@idfix.nl.mbx.txt
Tue Nov 12 15:15:12 2024 5

- Commit (18): 22,941

So it looks like you're using a lot of scheduled messages, either directly or indirectly (e.g. via redelivery delay), and the records related to the delivery schedule are accumulating. If you stop the broker and run the "journal compact" command does the number of records in the database drop?

Out of curiosity, is there a specific reason you're using JDBC vs. the traditional file-based journal on local disk?

Justin

Hi Justin,

Thanks again for your valuable insights.

We do use indirect scheduled messages intensively since we have
redelivery-delay=1000, redelivery-multiplier=2, redelivery-attempts=9
settings for the majority of queues. We also use
message-counter-history-day-limit=10 for all queues if that is at all
significant.

We have not tried explicit compacting the journal yet and since the
AMQ-related tables on production environments that ran into this
situation were truncated to get things back up we can not do this right now.
I was under the impression that Artemis also compacts the journal during
startup. If that is true could we not simply try restarting the Wildfly
server if we see large journal volumes to check if that makes a
difference, or is that not the same? If so, could you elaborate a bit
since I know how to stop/start the broker from the JBoss CLI but have no
knowledge about an explicit journal compaction command.

We use JDBC persistence for a couple of reasons. Having the journal
inside the database makes it easier for us to keep things in sync with
backups/restores which we also use heavily for trouble shooting. In
addition to that using file based persistence comes with additional
costs in our cloud environments.

Silvio

settings for the majority of queues.

I assume you're referring to redelivery-delay-multiplier and
max-delivery-attempts here.

> We also use message-counter-history-day-limit=3D10 for all queues if that
is at all significant.

I don't think that is relevant here.

> We have not tried explicit compacting the journal yet...

I had a look through the JDBC code and I see now that compaction is a red
herring. The normal file-based journal is append-only which is why it
requires occasional compaction. However, JDBC is not append-only. Records
are removed during normal processing, including the
set-scheduled-delivery-time records that are accumulating in your database.
I tested this with both 2.16.0 and 2.38.0 (i.e. the latest) and I didn't
see any accumulation. As soon as the message associated with the
set-scheduled-delivery-time records was acknowledged all those records were
cleaned up.

In any case, I don't believe that WildFly even supports the "data compact"
command so it would almost certainly be a head-ache to execute it.

To be clear, I typically only recommend folks use the embedded broker in
WildFly for the most trivial use-cases. As soon as complexity increases
it's usually good to have a standalone broker which can be managed (e.g.
upgraded, restarted, etc.) separately.

> I was under the impression that Artemis also compacts the journal during
startup.

Despite the fact that compaction doesn't appear to be related here I just
wanted to say that I don't believe the broker always compacts the journal
at startup. What gave you that impression?

Ultimately I'm not sure what's going on here. I'd need to be able to
reproduce the problem myself for further investigation. Do you have a way
to reproduce this problem?

Justin

I remember an old issue where rescheduling deliveries were updated over and over.

As of the latest version as far as I remember I only update it once.

If you have an infinite redelivery without DLQ you might get into that situation.

It would be difficult for me to find the exact JIRA now. But I will try to look for it and will post it here if I find it.

This sounds similar to an issue involving duplicate IDs proliferating in the journal. I can't find the specific Jira at the moment, but the issue was something like a huge build-up of duplicate ID records. Can you inspect the "userRecordType" for the offending rows?

Also, how are you sending your message exactly? Do you need duplicate detection?

Lastly, 2.16.0 is quite old at this point. There's been improvements to JDBC since then which you'd almost certainly benefit from (not to mention all the other bug-fixes and features). Are you open to upgrading?

Justin

Subject: Question regarding problems with JDBC persistence

-----YzUlPTE15gNZ2DCWOWswCX0F
Content-Type: text/plain; charset=UTF-8; format=flowed
Content-Transfer-Encoding: 7bit

Hello,

Inside Wildfly 23.0.0 we are running ActiveMQ Artemis Message Broker 2.16.0 with JDBC persistence on SQLServer for ~25 message queues. In some production environments we have moderate-to-high message volumes and since processing can be relatively slow temporary message pileup is not uncommon.

In one particular environment we are experiencing OutOfMemory issues during startup. There are about 60K messages in 2 of the queues while the message table contains over 350M records causing memory exhaustion during startup. Running in a controlled environment with ~60G heap startup succeeds and through JProfiler we observe that all message table records are selected and appear to be collected in memory. After that they are processed and discarded dropping memory usage down to a fraction of its peak. Using the JBoss CLI to inspect the queues then shows we have indeed 60K messages in 2 queues.

Inspecting the contents of the message table we see limited counts of record types 13 (ADD_RECORD_TX) and 14 (UPDATE_RECORD_TX) roughly equivalent to the 60K message count. All remaining records are type 11 (ADD_RECORD).

When we removed all type 11 records restart was fast with limited memory load and we still see 60K messages in the 2 queues.

In the past we have observed similar numbers and startup problems in other environments which lead us to truncate the AMQ persistence tables to be able to restart the server without an OutOfMemoryException. But we are looking for a way to prevent this situation from happening.

So my questions are:

- Is the large record count in the message table expected behavior?
- Is there anything we can/should do to limit the number of records in the message table?
- Is removing all type 11 records a valid workaround? If no, what would be the side-effect?

Thanks for your help!

Silvio
